

ABSTRACT OF THE DISCLOSURE

5 A rail groove is provided on an outer peripheral portion of a focus
adjusting ring. A lens seat, supporting an image pickup lens, is attached to an
escutcheon forming a main body. A plurality of engaging protrusions, provided
on a front surface of the escutcheon around the lens seat, engage with the rail
groove. Cam surfaces, formed on the focus adjusting ring, are brought into
10 contact with protrusions of a bracket which mounts an imaging element. The
rotational motion of the focus adjusting ring is converted into a linear or
progressive motion of a bracket by the cam surfaces.
